

A Model of Magnetic Monopoles

Rainer W. Kühne

e-mail: kuehne@theorie.physik.uni-wuppertal.de

The possibility of the existence of magnetic charges is one of the greatest unsolved issues of the physics of this century. The concept of magnetic monopoles has at least two attractive features: (i) Electric and magnetic fields can be described equivalently. (ii) In contrast to quantum electrodynamics models of monopoles are able to explain the quantization of electric charge. We suggest a quantum field theoretical model of the electromagnetic interaction that describes electricity and magnetism as equivalent as possible. This model requires the cross-section of Salam's "magnetic photon" to depend on the absolute motion of the electric charge with which it interacts. We suggest a tabletop experiment to verify this magnetic photon. Its discovery by the predicted effect would have far-reaching consequences: (i) Evidence for a new gauge boson and a new kind of radiation which may find applications in medicine. (ii) Evidence for symmetrized Maxwell equations. (iii) Evidence for an absolute rest frame that gives rise to local physical effects and violation of Einstein's relativity principle.

PACS numbers: 14.80.Hv, 12.60.Cn

The quantization of electric charge is well-known since the discovery of the proton in 1919. This remarkable observation remained unexplained.

Further quantized charges have been established. The group $SU(2)_w$ of the weak interaction explains the quantization of isospin, and the group $SU(3)_c$ of the strong interaction explains the quantization of colour charge.

For this reason we propose the "analogy postulate": "The quantization of electric charge results from the underlying group structure of the electromagnetic interaction." Hence, we will require neither quantum gravity (electric charge as a topological quantum number), nor spontaneous symmetry breaking (monopoles of soliton type^{1,2}), nor unification with other forces (charge quantization resulting from the group structure underlying grand unified theories).

The electromagnetic angular momentum gener-

ated by the Lorentz force in a system consisting of a magnetic monopole and an electric charge is independent of their separation³. Angular momentum is quantized in units of $\hbar/2$, where $\hbar = h/2\pi$ denotes Planck's constant. This condition can be satisfied only if both electric and magnetic charge are quantized⁴. This is the famous Dirac quantization condition $eg = h$, where e and g denote unit electric and unit magnetic charge.

Magnetic monopoles were discussed long before this finding. The motivation was to describe electric and magnetic fields equivalently by symmetrized Maxwell equations. We will elevate this to the "symmetry postulate": "The fundamental equations of the electromagnetic interaction describe electric and magnetic charges, electric and magnetic field strengths, and electric and magnetic potentials equivalently."

Dirac⁴ was the first to write down these symmetrized Maxwell equations. Let $J^\mu = (P, \mathbf{J})$ denote the electric four-current and $j^\mu = (\rho, \mathbf{j})$ the magnetic four-current. Furthermore, we require the well-known four-potential $A^\mu = (\Phi, \mathbf{A})$ and a new four-potential $a^\mu = (\varphi, \mathbf{a})$. Expressed in three-vectors Dirac's symmetrized Maxwell equations read,

$$\nabla \cdot \mathbf{E} = P \quad (1)$$

$$\nabla \cdot \mathbf{B} = \rho \quad (2)$$

$$\nabla \times \mathbf{E} = -\mathbf{j} - \partial_t \mathbf{B} \quad (3)$$

$$\nabla \times \mathbf{B} = +\mathbf{J} + \partial_t \mathbf{E} \quad (4)$$

and the relations between field strengths and potentials are

$$\mathbf{E} = -\nabla\Phi - \partial_t \mathbf{A} - \nabla \times \mathbf{a} \quad (5)$$

$$\mathbf{B} = -\nabla\varphi - \partial_t \mathbf{a} + \nabla \times \mathbf{A}. \quad (6)$$

The second four-potential is required not only by the symmetry postulate, but also by the proven impossibility to construct a manifestly covariant one-potential model of quantum electromagnetodynamics⁵⁻⁸.

Although only one of the suggested two-potential models^{4,9-15} explicitly states the possibility of the existence of a "magnetic photon" (ref. 15), the other two-potential models were eventually considered as two-photon models¹⁶.

Any viable two-photon concept of magnetic monopoles has to satisfy the following conditions.

(i) In the absence of both magnetic charges and the magnetic photon field, the model has to regain

the $U(1)$ gauge symmetry of quantum electrodynamics.

(ii) In the absence of both electric charges and the photon field, the symmetry postulate requires the model to yield the $U'(1)$ gauge symmetry of “quantum magnetodynamics”.

(iii) The gauge group has to be Abelian, because the photon carries neither electric nor magnetic charge. Because of the symmetry postulate also the magnetic photon has to be neutral.

(iv) The gauge group may not be simple, because quantum electromagnetodynamics includes the two coupling constants $\alpha_E = e^2/4\pi \simeq 1/137$ and $\alpha_M = g^2/4\pi = 1/4\alpha_E \simeq 34$.

The only gauge group that satisfies these four conditions is the group $U(1) \times U'(1)$.

A two-photon model has already been suggested by Salam¹⁵. According to his model the photon couples via vector coupling with leptons and hadrons, but not with monopoles. The magnetic photon couples via vector coupling with monopoles and via tensor coupling with hadrons, but not with leptons.

This model came under severe criticism. Although positron and proton have the same electric charge and no magnetic charge, the model can discriminate them (i. e. leptons and hadrons). For this reason Salam’s model does not generate the Lorentz force between electric charge and monopole. As a consequence, it does not satisfy the powerful Dirac quantization condition. For this reason Salam’s model was rejected by Taylor¹⁶.

The problem raised by Taylor can be overcome by the following argumentation. Salam considered the tensor coupling of the hadron-monopole system as derivative coupling. This kind of coupling is well-known from meson theory where vector mesons are able to interact with baryons via both vector and tensor coupling. However, derivative coupling is possible only where the particles are composite. Hence, Salam’s model includes no interaction between lepton and magnetic photon. – We emphasize the correctness of the interpretation of tensor coupling as derivative coupling in meson theory.

To generate the Lorentz force between electric and magnetic charges we have to introduce a new kind of tensor coupling. This is required also, because here we have two kinds of interacting charges (electric and magnetic).

The Coulomb force between two (unit) electric charges is $e^2/4\pi r^2$. Because of the symmetry postulate the magnetic force between two (unit) mag-

netic charges is $g^2/4\pi r^2$. And the Lorentz force between (unit) electric and (unit) magnetic charge is $egv/4\pi r^2$, where v denotes the relative velocity of the two charges.

This suggests the introduction of “velocity coupling”:

(i) The photon couples via vector coupling with electric charges.

(ii) The magnetic photon couples via vector coupling with magnetic charges.

(iii) The photon couples via tensor coupling with magnetic charges. In contrast to meson theory, however, the u^μ of tensor coupling, $\sigma^{\mu\nu}u_\nu$, has to be interpreted as a four-velocity (“velocity coupling”).

(iv) The magnetic photon couples via tensor coupling (interpreted as velocity coupling instead of derivative coupling) with electric charges.

In the case of the interacting monopole-electric charge system the exchanged boson (either photon or magnetic photon) is virtual and the four-velocity of velocity coupling is the relative four-velocity between the charges.

Charged quanta are required to emit and absorb the same bosons as real (on-mass-shell) particles as those virtual (off-mass-shell) bosons via whom they interact with other charged quanta. This is because the Feynman rules are symmetric with respect to virtual and real particles.

In the case of emission and absorption reactions of real bosons, u^μ cannot be interpreted as a relative four velocity between charged quanta in the initial state, as there is only one charged quantum present. As a consequence, u^μ has to be interpreted as the absolute four-velocity of the initial charged quantum.

In contrast to general belief an absolute rest frame is not forbidden. Instead, a number of reasons support its existence.

(i) General relativity gives rise to an expanding universe and therefore to a finite-sized light zone. The center-of-mass frame of this Hubble sphere can be regarded as a preferred frame.

(ii) According to Bondi and Gold¹⁷ a preferred motion is given at each point of space by cosmological observations, namely the redshift-distance relation generated by the superposition of the Hubble and the Doppler effect which is isotropic only for a unique rest frame.

(iii) The dipole anisotropy of the cosmic microwave background radiation due to the Doppler effect by the Earth’s motion was predicted in accordance with Lorentz invariance^{18,19}. This “aether

drift" of the Earth was later discovered²⁰ and measured to be $v_{earth} = 370 \text{ km/s}$ ($\pm 30 \text{ km/s}$, because of the Earth's motion around the Sun).

Now we have the tools to construct the Lagrangian for a spin 1/2 fermion field Ψ of rest mass m_0 , electric charge Q , and magnetic charge q within an electromagnetic field. By using the tensors

$$F^{\mu\nu} \equiv \partial^\mu A^\nu - \partial^\nu A^\mu \quad (7)$$

$$f^{\mu\nu} \equiv \partial^\mu a^\nu - \partial^\nu a^\mu \quad (8)$$

the Lagrangian of the Dirac fermion within the electromagnetic field reads,

$$\begin{aligned} \mathcal{L} = & -\frac{1}{4}F_{\mu\nu}F^{\mu\nu} - \frac{1}{4}f_{\mu\nu}f^{\mu\nu} \\ & + \bar{\Psi}i\gamma^\mu\partial_\mu\Psi - m_0\bar{\Psi}\Psi \\ & - Q\bar{\Psi}\gamma^\mu\Psi A_\mu - q\bar{\Psi}\gamma^\mu\Psi a_\mu \\ & + Q\bar{\Psi}\gamma^5\sigma^{\mu\nu}u_\nu\Psi a_\mu \\ & + q\bar{\Psi}\gamma^5\sigma^{\mu\nu}u_\nu\Psi A_\mu. \end{aligned} \quad (9)$$

By using the Euler-Lagrange equations we obtain the Dirac equation

$$\begin{aligned} (i\gamma^\mu\partial_\mu - m_0)\Psi = & (Q\gamma^\mu A_\mu + q\gamma^\mu a_\mu \\ & - Q\gamma^5\sigma^{\mu\nu}u_\nu a_\mu \\ & - q\gamma^5\sigma^{\mu\nu}u_\nu A_\mu)\Psi. \end{aligned} \quad (10)$$

By introducing the four-currents

$$J^\mu = Q\bar{\Psi}\gamma^\mu\Psi - q\bar{\Psi}\gamma^5\sigma^{\mu\nu}u_\nu\Psi \quad (11)$$

$$j^\mu = q\bar{\Psi}\gamma^\mu\Psi - Q\bar{\Psi}\gamma^5\sigma^{\mu\nu}u_\nu\Psi \quad (12)$$

the Euler-Lagrange equations yield the two Maxwell equations

$$J^\mu = \partial_\nu F^{\nu\mu} = \partial^2 A^\mu - \partial^\mu\partial^\nu A_\nu \quad (13)$$

$$j^\mu = \partial_\nu f^{\nu\mu} = \partial^2 a^\mu - \partial^\mu\partial^\nu a_\nu. \quad (14)$$

Evidently, the two Maxwell equations are invariant under the $U(1) \times U'(1)$ gauge transformations

$$A^\mu \rightarrow A^\mu - \partial^\mu\Lambda \quad (15)$$

$$a^\mu \rightarrow a^\mu - \partial^\mu\lambda. \quad (16)$$

Furthermore, the four-currents satisfy the continuity equations

$$0 = \partial_\mu J^\mu = \partial_\mu j^\mu. \quad (17)$$

The electric and magnetic field are related to the tensors above by

$$E^i = F^{i0} - \frac{1}{2}\varepsilon^{ijk}f_{jk} \quad (18)$$

$$B^i = f^{i0} + \frac{1}{2}\varepsilon^{ijk}F_{jk}. \quad (19)$$

Finally, the Lorentz force is

$$\begin{aligned} K^\mu = & Q(F^{\mu\nu} + \frac{1}{2}\varepsilon^{\mu\nu\rho\sigma}f_{\rho\sigma})u_\nu \\ & + q(f^{\mu\nu} + \frac{1}{2}\varepsilon^{\mu\nu\rho\sigma}F_{\rho\sigma})u_\nu, \end{aligned} \quad (20)$$

where $\varepsilon^{\mu\nu\rho\sigma}$ denotes the totally antisymmetric tensor.

This model does not contain any free parameters. Hence, it allows clear and decisive predictions for its verification.

The absolute rest frame predicted above gives rise to local physical effects. In a terrestrial laboratory the interaction cross section of a real magnetic photon (with ordinary matter in the terrestrial rest frame) is predicted to be smaller than the one of a real photon of the same energy, the suppression factor is $(v_{earth}/c)^2 \simeq 1.5 \times 10^{-6}$. Hence, each reaction that produces photons does also create magnetic photons. Furthermore, magnetic photons are 7×10^5 times harder to create, to shield and to absorb than photons of the same energy.

A relatively simple experiment to verify this idea is to illuminate a metal foil of the diameter $(1 \dots 100)\mu\text{m}$ by a laser beam and to place a detector (photographic plate, charge coupled device, or photomultiplier tube) behind the foil to measure the intensity of the penetrating fraction of the beam.

The $U(1) \times U'(1)$ model predicts that in contrast to the photons majority of the magnetic photons penetrate the foil. This is because the penetration depth of photons of the visible light in metals is a few nanometers, whereas the one of magnetic photons is predicted to be a few millimeters. The detected intensity is predicted to be about 10^{-12} times the one of the original laser beam (depending on the efficiency of the detector, usually of order one for photons and as a consequence of order 10^{-6} for magnetic photons).

It will be of great benefit to perform the proposed experiment. The discovery of the magnetic photon by the predicted effect would have far-reaching consequences:

(i) Evidence for a new vector gauge boson and a new kind of radiation ("magnetic photon rays").

(ii) Indirect evidence for magnetic monopoles and therefore the explanation of the quantization of electric charge.

(iii) Evidence that the fundamental equations of the electromagnetic interaction are symmetrized Maxwell equations that are invariant under $U(1) \times U'(1)$ gauge transformations.

(iv) Evidence that the dipole anisotropies of both the cosmic microwave background and the cosmological redshift distribution (by the Hubble effect and the Doppler effect) define an absolute rest frame and that it gives rise to local physical effects. This means a violation of the relativity principle.

Rays of magnetic photons may find industrial applications. Their penetration depth in matter is predicted to be 7×10^5 times the one of photon rays of the same wavelength. As a consequence, rays of magnetic photons may become an appropriate means for testing of materials (to detect material errors). For the same reason, they may find applications in those clinical purposes which are presently the domains of X-ray, holograph and ultrasonic diagnostics.

It remains the task for further studies to examine the following issues. (i) The mass of the lightest magnetic monopole has to be calculated. According to the most simple approach it can be estimated to be $m_e g^2 / e^2 \simeq 2 \text{ GeV}$, where m_e is the electron mass²¹. (ii) The coupling constant of the monopole-monopole interaction is as large as $1/4\alpha_E \simeq 34$. It has to be examined how the arising difficulties that concern unitarity and non-locality can be solved. - A similar problem arose in meson theory. The coupling constant of the pion is as large as 14.4. The arising problems were solved by the quark substructure of hadrons. (iii) Einstein²² rejected the “luminiferous aether”, because special relativity does not require an absolute rest frame. It would be interesting to learn whether aether is possible in general relativity. (iv) The $U(1) \times U'(1)$ model has to be embedded in a Grand Unified theory. One may imagine the underlying group to be $SU(5) \times SU'(5)$, where the primed group describes the hypothetical magnetic photon, (chromo-)magnetic gluons and (iso-)magnetic W, Z, X, and Y bosons.
